Restarting a stuck pod

When a pod enters CrashLoopBackOff, Kubernetes is deliberately waiting longer between restarts. Delete the pod with kubectl delete pod and the controller recreates it within seconds. If it returns to the same state, the fault is in the container rather than the scheduler.

Rotating the database password

Rotate the credential in the secret store first, then update the Kubernetes secret, then restart the deployment so pods reload it. Doing these in the wrong order leaves pods holding a credential that no longer works.

Certificate expiry on the edge

A TLS handshake failure on the public endpoint usually means the certificate expired or the chain is incomplete. Browsers cache intermediates, so a page that loads in a browser can still fail from curl.

Memory limits and exit code 137

Exit code 137 is 128 plus signal 9, which is kill. The kernel out of memory killer stopped the process. Raise the memory limit on the deployment or find the leak.
